

WebBIZContacts: Contacts Management Using Virtual Subdomain Addresses

Abstract of the Disclosure

WebBIZcontacts stores, searches, retrieves, and presents virtual subdomain addresses with differing domain names where these virtual subdomain addresses have a person's name in the subdomain name and the addressed displayed webpages can show the person's contacts information.

There are two types of WebBIZcontacts. One stores VSAs in a database that when searched, use its VSAs to retrieve contacts information on the Internet. The second had already selectively extracted the VSAs' contacts information from the Internet and stores this information data into a searchable database.

There are many embodiments of these types depending on where the virtual subdomain addresses are stored and what type of communications occurs between the search facility and the virtual subdomain servers.

WebBIZcontacts joined with virtual subdomain addresses form a powerful contacts manager. Virtual subdomain addresses enable a brief and preferred address to communicate a person's identity (WebBIZcard); while, WebBIZcontacts enables for the search, retrieval, and storage of WebBIZcards.
